

Fertility transition, 2007–2023

An initial replacement benchmark; a preference decline announced in 2007.

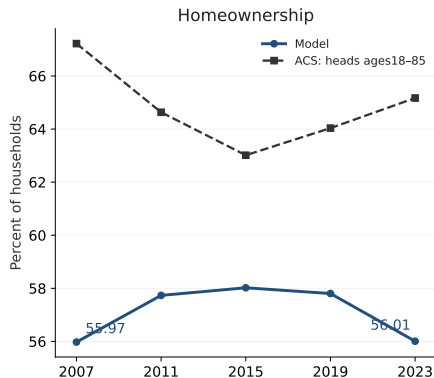

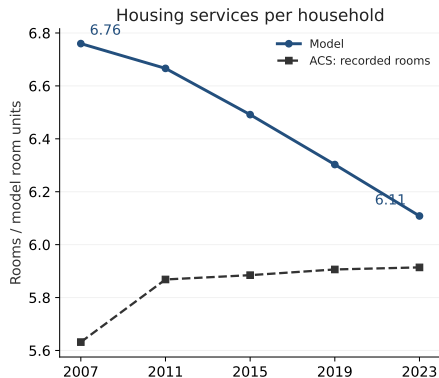

Across the four-year windows: fertility falls **13.2% in the model**, versus **16.7% in the data**.

Illustrative shock, not estimated; short-path equilibrium with an unverified long horizon. Initial 2.1 denotes completed fertility; transition points use the model birth-flow index.

Housing along the same transition

The fertility experiment also produces testable housing and tenure paths.

Ownership remains too low; model housing space falls from **6.76 to 6.11** room units.

National household heads ages 18–85. Recorded ACS rooms have changing top-codes; that series is descriptive, not a harmonized room-growth target. Household totals and age shares are imposed through 2023.
